Retrofitting Code into Embedded Binaries
BlueRISC, Inc.

**WHAT**

**Operational Need and Improvement:** Effectively securing the growing array of embedded devices in use on defense platforms is a critical challenge. Future remote-controlled and autonomous embedded devices play a central role in critical infrastructure and control key mechanical systems in the industrial, energy, and transportation sectors. In such applications, errors and vulnerabilities in the software running on these devices can have devastating impacts due to their ability to cause failures in the physical world. ThreatSCOPE CI not only performs an automated vulnerability characterization of these embedded software components, without the requirement of source code, but also enables the user of the tool to insert functionality into the software for the purpose of cyber-hardening or otherwise (e.g., new functionality in legacy systems, etc.).

**Specifications Required:** Critical embedded systems must be hardened against cyber-attack. For many of these systems (e.g., legacy), source code and/or a relevant development environment is not easily obtainable. Additionally, the insertion of codes (for cyber-hardening or otherwise) can have an impact on performance which must be managed.

**Technology Developed:** ThreatSCOPE Code Injection (CI) is a binary-level, vulnerability analysis toolkit (i.e. no source code required) enabling automated insertion of code into embedded executables/firmware. It provides vulnerability and performance guidance for the insertion of generic and cyber-hardening codes via an interactive GUI. The tool ensures that the inserted code operates within the existing constraints of the embedded software maintaining intended functionality while minimizing performance overhead. ThreatSCOPE CI has been validated on real-world embedded firmware (e.g., Apache web server, avionics Operational Flight Program - OFP) and shown to enable the patching of identified vulnerabilities (e.g., Heartbleed).

**Warfighter Value:** ThreatSCOPE CI enables vulnerability analysis and cyber-hardening of embedded software without the requirement of source code. The solution is directly applicable to a number of military and commercial embedded systems including unmanned systems (e.g., drones), avionics, industrial control systems as well as legacy embedded systems. ThreatSCOPE CI will give warfighter's assurance that mission-critical embedded systems can be hardened against malicious cyberattacks while maintaining operational mission functions.

**HOW**

**Projected Business Model:** Since 2002, BlueRISC has worked with the government to provide innovative solutions to cutting-edge problems in the cyber-security space. BlueRISC will license the ThreatSCOPE CI toolkit to large system integrators for utilization with Navy and DoD platforms, such as unmanned aircraft, avionics systems and embedded control systems. BlueRISC will provide users with full documentation, as well as example use-cases, on how to use the ThreatSCOPE CI toolkit. BlueRISC has commercialized toolkits resulting from SBIR efforts in the past and will leverage its existing online and licensing infrastructure. These toolkits have been sold worldwide in more than 15 countries.

**Company Objectives:** Binary-level compilation, exploitability analysis and cyber-hardening are core competencies of BlueRISC, making this Navy effort align directly with its corporate direction. BlueRISC’s expertise and relationships in these domains will ensure the success of the solution beyond this SBIR Phase I effort. BlueRISC will employ a multi-pronged strategy, via existing partnerships in the defense space, to transition the ThreatSCOPE CI toolkit to Navy programs as well as the broader DoD market. BlueRISC will also leverage existing relationships in the industrial control space (specifically the energy sector) to commercialize the tool outside of the government.

**Potential Commercial Applications:** ThreatSCOPE CI is expected to further the software assurance field by enabling the retrofitting of embedded firmware with cyber-hardening codes at exploitability relevant locations. The project is an ideal fit for BlueRISC and will provide a strong opportunity to not only target government programs but to also transition the technology to the commercial sector, specifically targeting embedded systems. BlueRISC will target embedded systems in the commercial space (e.g., drones, Internet-of-Things - IoT, Industrial Control Systems - ICS, etc.) via a cloud-based rental model enabling broader adoption in an easy-to-use and cost-effective manner.
